MRI LUMBAR SPINE (WITHOUT CONTRAST)

Patient: John Doe
DOB: 02/14/1980
Ref. Physician: Dr. Aris Thorne

Date of Exam: 03/15/2026
Accession #: MRI-9921-JD
DOL: 02/14/2026

CLINICAL INDICATION:

46-year-old male with persistent lower back pain and left-sided radiculopathy following high-velocity MVA on 02/14/2026. Evaluate for disc herniation and nerve root impingement.

TECHNIQUE:

Multiplanar, multisequence MR imaging of the lumbar spine was performed without the administration of intravenous contrast.

FINDINGS:

L1-L2 through L3-L4: Disc height and signal are preserved. No significant canal or foraminal stenosis.

L4-L5: There is a 5mm left paracentral focal disc protrusion (herniation). This results in moderate narrowing of the left neural foramen and appears to contact/impinge the descending left L5 nerve root. There is associated mild facet arthropathy.

L5-S1: Mild degenerative disc desiccation noted. No significant herniation or stenosis identified.

IMPRESSION:

- 5mm focal disc protrusion at L4-L5 with associated impingement of the left L5 nerve root. This correlates with the patient's reported clinical radiculopathy.**
- Mild degenerative changes at L5-S1.**
